

Follow This One Unique Method Before Harvest To Guarantee Cleaner, Tastier And Much More Potent Crops!

Every grower knows our plants feed by absorbing compounds from nutrients, water, and the atmosphere. . . but it's this very same process that can mean **BIG** problems because your plants can easily become polluted from the very places they're feeding from!

If You've Ever Coughed Your Lungs Out After Enjoying Your Plants, Pollution In Your Crops May Be The Reason Why!

As your plants age, they accumulate excess nutrient salts and other substances that decrease the quality and value of your product.

At times, this accumulation is visible as over-fertilization or other crop failures. More often, it is unseen, infiltrating your crops from the inside. This causes offensive crop taste and odor, crops that burn with black ash or are hard to keep lit, and crops that irritate and damage your respiratory system.

But there's a solution . . .

You Need To Flush Your Crops Before Harvest For Maximum Results!

Flushing is a simple yet powerful process that cleanses your crops just before harvest so you get:

- Cleaner, Safer Crops . . .
- Tastier, Sweeter-Smelling Crops . . .
- Higher Quality Crops That Command Premium Market Prices. . . but ...

Most Flushing Methods Don't Work!

Unfortunately, most forms of flushing, or the use of all-organic fertilizers, do not purge crops of harsh residues.

The most common way growers flush their crops is by giving their crops water with no nutrients in it. But this doesn't fully cleanse your crops. It starves your plants so they lose floral growth and resin percentages before harvest. Other growers use flushing formulas that consist of a few chemicals that sometimes have the ability to pull little residues out of your plants. These flush formulas remove plant nutrition, resulting in smaller harvests and decreased harvest potency. Not only that, but they don't provide the full-spectrum, value-enhancing cleanse you're looking for.

What your plants store comes from fertilizers, water, and the atmosphere. Organic fertilizer has no crop-cleansing properties in and of itself. Fortunately, there's a better way to ensure your harvests are crystal-pure.

Here's Your Step-By-Step Guide To Flushing Your Crops Before Harvest

The process of cleansing your flowers begins 4 to 10 days before you intend to cut them for harvest. At that time, you drain your reservoir, fill it with fresh water, and add just one formula: **FINAL PHASE**, the only flushing formula ever designed and tested to provide complete, value-enhancing cleansing of the specific type of plants we grow.

The fact **FINAL PHASE** is the only formula made for our plants is important because different species of plants respond differently to pre-harvest flushing.

After you have added **FINAL PHASE** to your plants' water

supply, you continuously irrigate your plants' roots for six hours to completely wash your roots and root zone. Then, you drain your reservoir and fill it with clean water. You do not add any nutrients or other supplements to your water supply. You just feed your plants pure water until harvest time.

As proven by thousands of tissue samples taken from the exact type of plants we grow, this procedure results in crops almost totally purged of excess salts and other burdens!

Here's The Unique 7-Step Method That Increases The Value of Your Harvest . . .

If you could see down to the molecular level, here's the amazing process in action:

1. **FINAL PHASE** contains a special ingredients known as a "chelate" . . .
2. Chelates are like chemical "claws" that can grasp other materials, such as individual nutrients, and bind to them . . .
3. During the course of the six-hour **FINAL PHASE** cleansing, the formula's proprietary, exceptional chelate removes excess nutrient salts, heavy metals and pollutants from your plants' roots and their root zone . . .
4. Some of the chelate enters your plants and creates a downward mobility of excess salts that exit your plants and are washed into the **FINAL PHASE**/water solution . . .
5. After the **FINAL PHASE**/water mixture has done its job, you remove all that water from your reservoir and refill your reservoir with fresh water . . .
6. Inside your plants, from the time of flushing until harvest time, your plants are consuming on-board nutrients and otherwise purging themselves of unwanted residues. . .
7. By the time you harvest, your plants will be free of at least 85% of the stored materials they held before flushing . . .

Also, **FINAL PHASE** is 100% guaranteed, as always, if for any reason you're not absolutely delighted we'll refund your money back. It's that simple.

Read what growers are saying about Final Phase!

 **Calvin, Compton, California** "It had gotten so bad that I couldn't even keep the stuff lit. I thought it was too wet or something. But when I started doing the flushing, then I saw what had been happening. Too much phosphates were left in. The flushing got rid of it. Thanks."
August 2011

 **Christopher Kisner** "Final Phase flushes built up salts and nutrients for a fresh, clean taste."
June 22 2011

 **Sean Fries** "I can't recommend it enough. It's an amazing product. I started with Iguana Juice to Big Bud to Bud Candy and then Final Phase."
September 15 2011
